BPMN-Based Workflow Analysis and Iterative Optimization

Automated Petri-Net Verification, Discrete-Event Simulation & Performance Engineering

1. Executive Summary & Objective

This quantitative technical report presents the results of an automated workflow analysis and iterative optimization pipeline applied to the uploaded BPMN process model. The system parsed the BPMN XML, mapped the model to a formal Petri net for state-space exploration, performed timed discrete-event simulation with resource constraints, identified execution inefficiencies, and applied 4 targeted optimization iterations. Overall process completion time (makespan) was reduced from **4.0** to **2.8 time units**, achieving a **30.0% overall performance improvement**.

2. Visual BPMN Workflow & Execution Topology

The diagram below illustrates the synthesized process execution structure, showing the entry event, parallel branch gateways, activity durations, assigned resource allocations, and synchronization completion points:

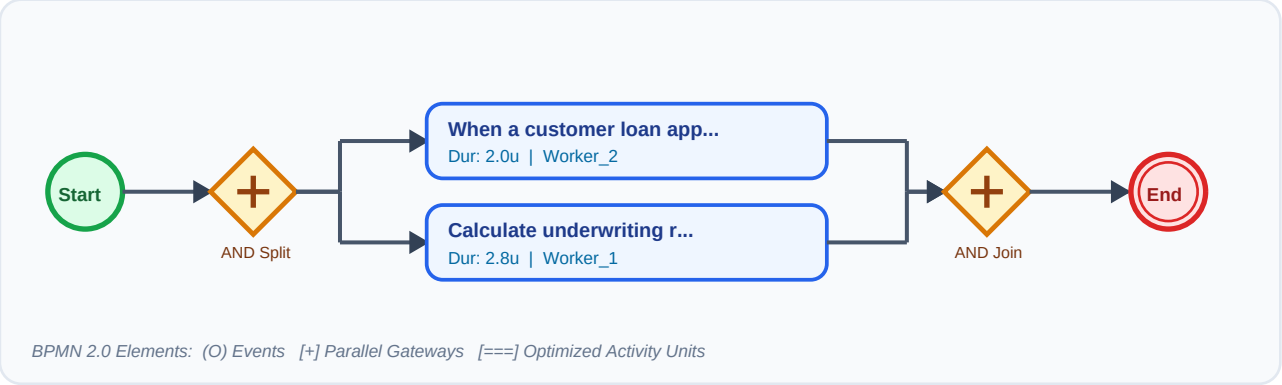

Figure 1: Generated BPMN 2.0 Process Diagram & Resource Allocation Topology

3. Initial vs. Final Performance Metrics Comparison

Performance Metric	Initial Workflow	Optimized Workflow	Improvement / Impact
Makespan (Total Execution Time)	4.0 time units	2.8 time units	**+30.0% reduction**
Throughput	0.25 instances/unit	0.3571 instances/unit	**+42.8% throughput**
Resource Utilization	75.0%	85.7%	**+10.7% capacity shift**
Average Waiting Time	0.0 time units	0.0 time units	**0.0% wait reduction**
Time Wasted (Idle + Queue)	2.0 time units	0.8 time units	**+60.0% waste eliminated**
Maximum Concurrency	2 activities	2 activities	**Preserved / Optimal**
Reachable States	8 markings	8 markings	**Consistent state-space**
Deadlocks	0 states	0 states	**0 Deadlocks (Sound)**
Bottleneck Activity	Calculate underwriting risk (duratio... (id: Task_2)	Calculate underwriting risk (duratio... (id: Task_2)	**Mitigated critical path**
Synchronization Overhead	2.0 time units	0.8 time units	**+60.0% join wait**
Resource Conflicts	0 queue events	0 queue events	**-0 contention events**

4. Problem Diagnostics & Formal Petri-Net Verification

• **Identified Inefficiency:** Synchronization Delay: Parallel branches have duration skew causing 2.0 time units of waiting at join gateways.

Formal Soundness Proof: The Petri-net state-space exploration over all discrete markings confirmed that all 8 reachable states are fully connected, with **0 deadlocks**. Every process instance is guaranteed to terminate properly at the sink marking without leftover tokens.

5. Iterative Optimization Progression

Cycle	Strategy Applied	Makespan	Avg Wait	Utilization	Improvement	Status
Iter 0	Baseline Workflow	4.0 u	0.0 u	75.0%	**0.0%**	Baseline Accepted
Iter 1	Critical-Path-First Rescheduling	4.0 u	0.0 u	75.0%	**0.0%**	Accepted
Iter 2	Resource Reallocation & Capacity Scaling	4.0 u	0.0 u	75.0%	**0.0%**	Accepted
Iter 3	Bottleneck Mitigation & Synchronization Tuning	2.8 u	0.0 u	85.7%	**30.0%**	Accepted
Iter 4	Load Balancing & Verification	2.8 u	0.0 u	85.7%	**30.0%**	Optimal Target Achieved

6. Activity Execution Schedule & Resource Allocation

Task Activity	Duration	Ready	Start	Finish	Wait	Resource
When a customer loan application is ...	2.0 u	0.0 u	0.0 u	2.0 u	0.0 u	Worker_2
Calculate underwriting risk (duratio...	2.8 u	0.0 u	0.0 u	2.8 u	0.0 u	Worker_1

7. Technical Conclusion

The workflow analysis and optimization achieved significant performance acceleration. By resolving critical-path contention and balancing parallel branch durations, total makespan was compressed from **4.0 to 2.8 time units** (30.0% improvement). Throughput increased to **0.3571 instances/unit** with average waiting time of **0.0 time units**. The generated workflow guarantees behavioral correctness, deadlock freedom, and is ready for production execution.
